Overview of My Role in Sprint 1

During Sprint 1, I was mainly responsible for handling documentation and also contributing to the coding part related to user management through the administrator. Throughout this period, I learned that structuring documentation in a software development team environment can be quite challenging.

User Stories and User Acceptance Tests

I gained experience in writing user stories based on actual system requirements and converting them into clear user acceptance tests. I also learned how to materialize something that we call a traceability matrix, so that we make sure that every requirement is linked to a user story that is going to be divided into tasks and coded later on into real software.

Requirements Traceability Matrix

The requirement traceability matrix, I did mention that, okay, I developed an understanding of the requirements, and this helped me see how every requirement in the system can link to every code block that is implemented. The process ensured that nothing was missed, and we did that in an iterative manner.

System Development (Role-Based Access Control)

As we go through system development role-based access, I implemented the side of the user where the administrator can be able to manage the roles and manage all the users in the system. They were able to assign different roles, which were applicant, provider, and admin to other admins too. And then I also contributed to both the front end and the back end of that part.

Backend Implementation (update User Function)

For example, if we go to controllers.js in the back-end folder, I contributed to a part that is called. Let me just go to it quickly. I contributed to a part that is called updateUser. I wrote it at exports.updateUsers, and then I implemented that back-end part there.

User Management Functionality (View, Search, Filter Users)

Before being able to update the user, I had to code an extra functionality that allows me to be able to view all users and filter them by role and also be able to search for users in real time. So that was also part of something that I had to do.

GitHub Team Collaboration

When we go to team collaboration in GitHub, it is one of the most challenging things because in a team environment, you have to work with very strict rules. For example, we use branches, and we have to be strict with developing our code and pushing it, and making sure that there are no major conflicts because pull requests were not getting approved if there were major issues, so that we can be able to protect the code that is in the main folder of the team.

Reflection on Sprint 1

As I am reflecting on sprint one, I enjoyed most of it as much as it was challenging and difficult, but I am looking forward to making it a much more enjoyable experience than it was now in sprint two and going forward. This showed me to understand the essence of software development and how it can play a role in real life, and to just show that it's not mainly about coding, but it's about understanding the problem and creating a solution to the problem before we even touch the computer itself.
